

Single-mode and multimode fiber parameters

Overview

Multimode fibre has two types of light propagation - step index and graded index, while singlemode fibre has only one step index.

Key Takeaways

Single mode fiber (SMF) has a small core for long-distance, high-bandwidth transmission, while multimode fiber (MMF) has a larger core for short-distance, cost-effective applications.

Core and Light Propagation

- Single Mode Fiber (SMF): Core diameter $\sim 9 \mu\text{m}$, cladding $125 \mu\text{m}$. Allows only a single light mode, reducing modal dispersion and enabling long-distance transmission .
- Multimode Fiber (MMF): Core diameter $50 \mu\text{m}$ or $62.5 \mu\text{m}$, cladding $125 \mu\text{m}$. Supports multiple light modes simultaneously, which can cause modal dispersion and limits distance .

Wavelength and Attenuation

- SMF: Typically uses 1310 nm or 1550 nm wavelengths. Lower attenuation, ideal for long-haul networks .

- MMF: Typically uses 850 nm or 1300 nm wavelengths. Higher attenuation, suitable for short-range, cost-sensitive setups .
Transmission Distance and Bandwidth
- SMF: Can transmit signals over miles without repeaters. OS1 fiber up to ~1.5 miles, OS2 up to 125 miles. Bandwidth typically 1-10 Gbps or higher .
- MMF: Effective for distances
